

Core Formatting Features

- **Formatting text:** This involves changing the appearance of characters within a cell. You can modify the **font style** (e.g., Calibri, Arial), **font size**, and apply emphasis like **Bold**, *Italic*, or Underline to make specific data stand out.
- **Apply borders and shading:**
 - **Borders:** Adds visible lines around a cell or a range of cells to define the grid or separate different sections of data.
 - **Shading (Fill Color):** Adds a background color to cells, which is often used to highlight headers or categorize rows.
- **Alignment and merge cells:**
 - **Alignment:** Controls where the text sits within the cell boundaries (top, bottom, left, right, or center).
 - **Merge cells:** Combines two or more adjacent cells into one large cell, which is commonly used for creating centered titles across multiple columns.
- **Change cell size:** This allows you to adjust the **width of columns** or the **height of rows**. This is necessary to ensure all text is visible or to improve the overall layout of the document.

Structure and Data Types

- **Insert, Delete Rows and Columns:** These commands let you modify the structure of your spreadsheet. **Inserting** adds a new blank row or column to accommodate more data, while **Deleting** permanently removes them and shifts the surrounding data to fill the gap.
- **Cell category:** This refers to setting the **Data Type** for a cell. By choosing a category (such as General, Number, Currency, Date, or Percentage), you tell Excel how to treat and display the information you've entered.
- **Increase or decrease decimal:** This tool specifically formats numerical data by controlling the number of digits shown after a decimal point. **Increasing** provides more precision, while **decreasing** rounds the number for a cleaner appearance.
